

Mahdi Heydari

Protocol Engineer & Security Researcher

abramsymons@gmail.com Muscat, Oman · Remote (GMT+4) abramsymons.github.io github.com/abramsymons
x.com/0xmahdi_

Protocol engineer with 15+ years in software and 8+ years designing decentralized systems: BFT sequencing, threshold cryptography (FROST, DKG), sybil-resistant identity, multi-chain custody and exchange engines. Designed the BrightID node, the Muon oracle network and the Zellular sequencing protocol. Prototypes new protocols, then ships on audited production cores (Zcash FROST, Firedancer Alpenglow). Security researcher with a \$30,000 Aptos bounty for a network-halting consensus bug.

SECURITY RESEARCH

Blockchain bug bounties · Independent

- Aptos:** \$30,000 bounty for a High-severity consensus vulnerability that could halt the network. Three more valid findings were closed as duplicates.
- Sui:** reported 8 vulnerabilities. 6 denial-of-service issues were confirmed as duplicates, 4 of them reachable by unauthenticated network peers. 2 more are under review.
- Zex custody (internal audit):** manually audited the FROST threshold-signing service and the multi-chain deposit and withdrawal modules: 17 findings, including several critical issues in key generation, signing and deposit detection.
- Muon:** reported 14 security and design flaws in the node and its threshold-signature library, including a rogue-key attack on distributed key generation and a single-node denial of service of key generation.

EXPERIENCE

Zex

2024 – present

Founder & Protocol Architect (2024 – 2025) → Tech Lead & Reviewer (2025 – present)

Multi-chain exchange that runs as a replicated state machine on a decentralized sequencer.

- Built Zex as the first application on the Zellular stack, combining Zellular sequencing, the decentralized custody service (as ZexPorta) and an orderbook service (Cora). It grew into a standalone exchange.
- Multi-chain threshold custody (ZexPorta):** designed how one validator group controls funds on every chain with FROST keys on secp256k1 (Taproot) and Ed25519. Bitcoin gets per-user Taproot addresses through key tweaking, with withdrawals that look like ordinary single-signature spends. EVM and Tron get CREATE2 deposit contracts and an ecrecover-based Schnorr verifier. Solana and Aptos verify Ed25519 natively. An independent "shield" key must co-sign every withdrawal, so a compromised threshold group still cannot move funds. Explored shielded Zcash custody with RedPallas FROST. Running on testnet, pre-mainnet.
- Built transaction authentication in the core engine: signing-key verification, replay protection, and a fork mechanism for deterministic protocol upgrades.
- Wallet-free onboarding:** designed OpenID Connect login without a custodial provider such as Privy. The user's session key is bound into the Google-signed token through the login challenge, and every replica verifies it, the same approach Aptos and Sui use for keyless accounts (ZIP-001). Also adapted passkeys, which are designed for client-server apps, to serverless replicated-state-machine apps: prototyped for BrightID and shipped as a Zex login option.
- Reviewed 90+ pull requests from 6 engineers across the engine, custody and transaction format.
- Matching engine at 1M orders/s (2026):** Zex launched against a 100K orders/s target. Redesigned the protocol so independent implementations agree exactly (canonical signed text, 128-bit bounds, a canonical state hash and conformance vectors), then prototyped an AI-assisted C engine verified against the Python engine by per-batch state digests. It reaches about 1M orders/s: 830K on a realistic deep book with 2,000 users and 20K price levels, about 25 times faster than Python.
- Production consensus (2026):** started `vseq` to replace the Zellular prototype with consensus extracted from production blockchains. It runs Firedancer's Alpenglow (votor) as a standalone ordering service with BLS12-381 finality certificates, a crash-safe ledger and a Python SDK that verifies finality proofs on the client. Designed it and directed an AI-assisted implementation in C.

AWARDS

1st place, EigenLayer AVS MicroHacks

2024 · \$12K prize, 100+ builders.
Python and JavaScript
EigenLayer SDKs.

100,000 EIGEN ecosystem grant

2024 · Eigen Foundation, for Zellular's EigenLayer work.

EDUCATION

B.S. Software Engineering

Shiraz University, 2010

SKILLS

Protocols

BFT consensus Sequencing
EigenLayer AVS Oracles

Cryptography

FROST DKG Schnorr BLS
OIDC / JWT

Security

Consensus review
Network DoS
Threshold-crypto attacks

Workflow

AI-assisted development
AI-assisted auditing

Languages

Python TypeScript
JavaScript Solidity

Chains

Ethereum Bitcoin Solana
Aptos Sui

Infrastructure

PostgreSQL Redis Kafka
Docker

Zellular · Founder & Protocol Architect

2023 – 2025

Decentralized infrastructure for running dApps as replicated state machines. Merged into Zex in 2025.

- Designed an architecture in which dApps rely on decentralized services for consensus and custody, so developers write only app logic and never manage keys or chain integrations.
- Sequencing:** designed the Zellular BFT protocol (leader-based, no proposer rotation or gossip, BLS-aggregated finality proofs, leader dispute and switchover). Built the prototype for 100K tx/s through batching, with sub-second finality, and ran it as an EigenLayer AVS with about 10 testnet operators. Core developer of zsequencer (250+ commits) and sole author of the `zellular.py` app SDK.
- Threshold custody, from protocol to product:** wrote the [pyfrost protocol specification](#) (DKG with verifiable secret sharing, rogue-key defense, and an analysis showing how naive complaint handling lets two colluders exclude honest nodes, which led to an identifiable-cheating DKG) and designed the library's node, key-generator and aggregator roles. Then designed zbtc (an EigenLayer-secured Bitcoin bridge) and EigenSync (verifying EigenLayer operator signatures on any EVM chain) as prototypes, and generalized them into a multi-chain custody service for exchanges, restaking platforms and payment apps, now ZexPorta at Zex. For production, replaced pyfrost's own cryptography with the Zcash Foundation's audited FROST, keeping the Python networking layer.
- EigenLayer tooling:** lead author of [eigensdk-python](#) (the Python port of EigenLayer's Go SDK, including slashing and rewards) and `avs-subgraph`. Co-built `eigensdk-js` and the Python reference AVS.

Muon Network

2021 – 2023

Architect (2021 – 2022) → **Technical Lead** (2022 – 2023)

Decentralized oracle network using threshold signatures. Grew to 3,400+ testnet operators and a 1,500+ node mainnet. [muon.net](#)

- Conceived and designed Muon's architecture as a decentralized price oracle for DEUS/Symmio, later generalized for any dApp.
- Chose threshold signatures from day one, when MPC was still rare in web3: hundreds of nodes produce one Schnorr signature that costs the same to verify on-chain however many nodes sign, where multisig gas grows with every signer.
- Modular security:** designed three layers dApps can combine. Threshold signatures give cryptographic security. An optimistic layer gives economic security: warrantor nodes lock collateral behind each response, supervisor nodes dispute bad data, and a DAO slashes dishonest warrantors. A shield lets an independent party re-verify each event and co-sign; if it misbehaves it can only stop the flow, never forge data.
- While reviewing the security of the large JavaScript node, decided a lean Python rewrite was safer than auditing it. Led about 6 engineers building it (`muon-frost-py`), teaching them the FROST protocol, along with the optimistic node and the explorer. Reviewed 77 core-node PRs.
- Started the developer documentation, and built a price-feed app and the node backup and deployment tooling.

BrightID · Core Team Developer

2018 – 2023

Social identity network that proves each user has one account. 73K+ verified users, integrated by 15 apps including Gitcoin Grants. [brightid.org](#)

- Primary architect and developer of the [BrightID node](#), which stores the social graph and serves verifications to apps. Wrote or reviewed most of its code (600+ commits).
- Designed the node consensus layer. Sequencing every user connection on Ethereum mainnet would have cost too much gas, so before sidechains and L2s existed we launched [IDChain](#), a dedicated proof-of-authority chain (geth Clique). Nodes replay graph operations in block order, so every node converges on the same social graph.
- Led anti-sybil research: SybilRank variants, a group-based ranking algorithm and a simulation platform for modeling attacks on the graph. Implemented the Bitu verification model (about 12K users verified by 2022).
- Designed and built blind-signature verifications, so apps can confirm a user is verified without linking the user's accounts across apps. Chose the scheme and libraries and implemented it in the node and the client.
- Co-designed and built the IDChain ecosystem: explorer, DEX, bridge to Ethereum and a gas faucet for verified users. Implemented social recovery and the verification contracts.

Freelance Software Engineer · Freelancer.com

2013 – 2018

- Co-ran a two-person development team: 220+ completed projects for international clients, averaging 4.8 / 5 across 228 reviews.
- Python automation, data processing and web scraping, web services and APIs, and server administration. Moved into Ethereum smart contracts and token sales from 2017.

Software Developer · City transit systems, Shiraz

2010 – 2013

- Built the back end, front end and driver settlement for the city bus fare system, used by hundreds of thousands of citizens paying with contactless cards on every bus.
- Made driver payments fail-safe with two independent calculation paths: one from passenger tap records, one computed by the bus reader at each driver shift change. Payment was held until both matched, so every discrepancy was found and fixed before money moved.
- Built an automatic vehicle location (AVL) system that tracks buses in real time, produces fleet reports, and announces next-bus arrival times at stations and on board.
